ABSTRACT OF THE DISCLOSURE

A digital history service presents a user's collected data in an historical format such as a timeline that includes various interactions with objects and people over the course of time wherein the digital history data was retrieved and correlated from the various data stores. An example of such a retrieval is to select a sequence of items from the data store based on an algorithm that determines the next item based on its relationship to the current item. The relationship could be a complex combination of the date, time of year, historical events in the past, the person(s) or objects involved in a given event, the location of an event, past or upcoming national holidays, calendar items, etc.
